

Figure 1: A section of a metal wire.

When applying a *voltage* across a metal wire, a *current* (designated as  $I$ ) will flow. A voltage can be seen as electric pressure between two points. A current can be seen as movement of electric particles in the wire, in this case electrons. Note that the electrons, having a negative charge, move in the opposite direction of the measured current (as shown by  $I_e$ ).

The resistance of a metal wire with length  $L$  and diameter  $d$  is:

$$R = \frac{\rho L}{A} \quad (1)$$

where  $A$  is the area of the cross section with

$$A = \frac{1}{4} \pi d^2 \quad (2)$$

and  $\rho$  is the specific specific resistance of the metal in  $\Omega \text{ m}$  (ohm meter).
